The results of an investigation of the graptolitic shale of Llandovery age along Øleå on Bornholm are presented. A section through the shale is made and the thickness of the Llandovery Series estimated to be between 110 and 130 m. 15 bentonite layers are reported. A revised zonation is proposed and discussed. The Llandovery Series comprises the *Rastrites* Shale and the lower part of the *Cyrtograptus* Shale. No marked transition is observed between the two shales and the subdivision of the Llandovery Series is abandoned.
