GORDILLO, Carlos E. 1965. Variaciones químico-mineralógicas en el contacto de una aplita con mármol dolomítico. *Boletín Academia Nacional de Ciencias*, XLIV: págs. 53 a 60. Córdoba (Argentina).

The chemical variations and the actual mineral assemblages across a contact between an aplite dike and an already metamorphosed dolomitic marble, are described..

At the contact zone can be recognized: (1) a primary endomorphic zone which is built essentially of plagioclase and diopside as minor accessory, (2) a secondary zone which is genetically related to the residual hydrothermal solutions derived from the intrusive body. These solutions operating through the boundary of the primary skarn have partially replaced the plagioclasic border by scapolite, and at the marble side they have produced a tremolitic layer. Across the contact the compositional changes have always produced nearly pure monomineralic layers. Chemical analysis of the fresh and altered rocks show the gains and losses of material during the replacement process.

GÓRECKI A., 1965: Energy values of the small mammal body. Acta
theriol., 10, 23: 333—352.

Energy values of the body were examined in 5 species of small mammals prevailing in the forest and field ecosystems: *Sorex araneus* L., *Apodemus flavicollis* (M e l c h.), *Apodemus agrarius* (P a l l.), *Clethrionomys glareolus* (S c h r e b.), and *Microtus arvalis* (P a l l.). A total of 270 samples derived from 220 animals caught in 3 seasons (late winter and prevernal season, summer, and autumn) were burned in the bomb calorimeter. The caloric value per gram dry weight and the per cent water and ash were determined and the cal/ash-free g values and the values of biomass were calculated. In the examined rodents the cal/g dry weight value is the lowest at the end of winter (4508.44 cal/g). In the summer it goes up rapidly to reach 5261.05 cal/g and a similar value is maintained in the autumn (5204.08 cal/g). The caloric value of the body for shrews does not show any seasonal changes, being low all the year round (4554.96 cal/g). The caloric value per gram ash-free weight exceeds by 10.2—13.7% the cal/g dry weight value, showing very similar specific and seasonal variations. The seasonal fluctuations and specific differences in these values depend mainly on the fatness and only slightly on the ash content. The energy value of biomass for all the species and seasons falls within a narrow range of 1601—1693 cal/g, with an average of 1501 cal/g. Consequently, either this mean value, 1.5 Kcal/g, will be used to calculate the productivity of populations of small mammals or the coefficient may be differentiated for seasons and species.

GÓRECKI A., 1966: Metabolic acclimatization of bank voles to laboratory conditions. Acta theriol., 11, 18: 399—407.

[Dept. Anim. Gen. & Org. Evolution, Kraków, Krupnicza].

The metabolism (oxygen consumption) was compared in the bank voles, *Clethrionomys glareolus* (Schreber, 1780) reared in the laboratory for several generations ("laboratory") and in voles captured in the field ("wild"). The general shape of temperature — metabolism curves in the range of +5 to +35°C was similar in laboratory and wild voles and their thermoneutral zone was around 30°C. The metabolism of laboratory voles was usually higher than in wild voles but the difference was statistically significant only in the temperatures 15 and 20°C during the winter and 10 and 20°C during the summer. In laboratory temperatures (15—25°C) the heat production was markedly lower in the laboratory voles, both in the winter and in the summer. The body insulation index in wild voles undergoes drastic seasonal changes, while in the laboratory voles it is quite similar in the winter and in the summer. Consequently, the models of wild rodents bioenergetics can not be based on the laboratory strains of these species.

IDENTIFICATION AND DETERMINATION OF PHENOLS
AND CHLOROPHENOLS IN VERY DILUTE AQUEOUS
SOLUTIONS BY GAS-LIQUID CHROMATOGRAPHY, PAPER
CHROMATOGRAPHY AND SPECTROPHOTOMETRY

P 912

After concentration of the organic substances from water samples of 700 to 20,000 l by adsorption on active carbon and desorption with chloroform in a large Soxhlet apparatus, the organic compounds were separated by extraction into 5 different groups: acids, phenols, bases, neutral and amphoteric substances. The phenol group was investigated by gas and paper chromatography, ultraviolet difference spectrophotometry and infrared spectroscopy. Phenol, 2,4,6-trichlorophenol, 2- and 3-cresol, 2,4-xyleneol and 2,4-dichlorophenol were identified in samples of raw and treated water. Quantitative measurements proved to be possible with gas chromatography. The conditions for quantitative desorption and separation were studied.

1968. Faunal and zoocenological analysis of the soil insect communities in the ecosystem of shelterbelt and field.

Warszawa, 1968, 24 cm., ill.

Ekologia Polska tom XVI nr. 14

Górny, M. 1968 – Dynamics of the soil insect communities in two biotopes of an agricultural landscape – Ekol. Pol. A, 16: 705–727.

Results are presented in this study of investigations of the qualitative differentiation and variations in population size of the soil insects of a shelterbelt and fields depending on the seasonal and annual variations in weather and micro-climatic conditions.

Gómy, M. 1968 – Faunal and zoocenological analysis of the soil insect communities in the ecosystem of shelterbelt and field – *Ekol. Pol. A*, 16: 297–324.

Qualitative and quantitative zoocenological analysis was made of soil insect communities of a shelterbelt, neighbouring fields and zones of the ecotone. Analysis of the soil entomofauna formed the basis for an attempt at comparing the biotopes examined with each other and arranging them in ecological order, and an attempt at evaluating the reciprocal influence of the biotopes of the shelterbelt and field.

Górny, M. 1968 – Synecological studies of the soil macroentomofauna in two different agricultural biotopes – Ekol. Pol. A, 16: 411–443.

The study presents the results of investigations of the soil macroentomofauna of a shelterbelt and fields. Analysis was made of the relationship between dominant species of the fields and the kind of crop and observations carried out on the adaptation of soil insect populations to the phenology of crops and the rhythm of the agrotechnical operations. The feeding habits of soil insects and their requirements in respect of habitat humidity were examined, and in the light of these observations, the spatial and vertical distribution of insect populations in the soil of the shelterbelt and field.
