L'étude métallographique et thermique de l'oxycoupage et du chanfreinage au chalumeau oxyacétylénique a permis de dégager les conclusions suivantes :

1. Les températures maximales dans le métal de base approchent de très près la température de fusion.

Contrat Euratom N° 090-62-12 RDF

Bruxelles, février 1966 - 88 pages - 41 figures - FB 125

Les essais entrepris au cours de l'étude ont abouti à un certain nombre de conclusions et d'observations que l'on peut résumer comme suit :

1. En présence d'un problème de soudage de tôles épaisses, par exemple de 200 mm ou plus, il est possible de procéder à la mise au point du mode opératoire de soudage, par le procédé de soudage à l'arc rivisagé, en opérant sur des prélèvements, dits «tranches», perpendiculaires à la peau. A partir d'une épaisseur de tranche de l'ordre de 60 mm, l'opération de soudage sur cette tranche est représentative de celle qui sera menée sur le produit du point de vue du cycle thermique, de la dureté et de la structure

ECONOMIC USEFULNESS OF RAISING THE PRIMARY CIRCUIT
CHARACTERISTICS OF A GRAPHITE-GAS POWER PLANT —
Final Report

European Atomic Energy Community — EURATOM

Report prepared by ALSTHOM

Société Générale de Constructions Electriques et Mécaniques,
Paris (France)

Contract EURATOM/AEG/ALSTHOM No. 009-63-12 TEGC

Brussels, March 1968 — 130 Pages — 52 Figures — FB 175

In the latter years the characteristic trend in graphite-gas nuclear power plants has been the shift of the cooling circuit from the outside to the inside of the reactor pressure vessel. This development became possible through the adoption of the prestressed concrete vessel. The greater safety afforded by the integrated design permits of higher operating temperatures and pressure than those in non-integrated reactors

With the heat exchangers inside the pressure vessel, however, the question arises as to whether it is preferable to choose a steam cycle that requires fewer runs through the vessel at the expense of efficiency, whether efficiency should be the principal aim.

GRAVIMETRIC AND SPECTROPHOTOMETRIC
DETERMINATION OF MERCURY WITH
N-BENZOYL-N-PHENYLHYDROXYLAMINE

N-Benzoyl-N-phenylhydroxylamine (BPHA) is suggested for the gravimetric determination of mercury(II) at pH 3.0–6.0; the precipitate, $\text{Hg}(\text{C}_{13}\text{H}_{10}\text{O}_2\text{N})_2$, is dried at 105° and weighed. Separation from NH_4^+ , Pb, Bi, Sb, As, Cd, Sn, etc. is possible, but chloride, cyanide and EDTA interfere. Mercury(II) can also be extracted with a BPHA solution in chloroform; the extracted mercury complex is yellow and shows an absorbance maximum at $340\text{ m}\mu$. The optimum concentration range for determination is $15\text{--}52\ \mu\text{g Hg/ml}$, the molar extinction coefficient is 2693 ± 10 and the sensitivity is $0.075\ \mu\text{g/cm}^2$. Interferences are similar to those found in the gravimetric method.

THE EURATOM COMPUTER LINKAGE SYSTEM by C. GREEN.

European Atomic Energy Community — EURATOM
Joint Nuclear Research Center — Ispra Establishment (Italy)
Scientific Data Processing Center — CETIS
(CETIS Report No 40)
Brussels, June 1963 — pages 12 — figures 4

This report describes a project for the construction of a system for the linkage of digital and analogue computers. It proposes two principles hitherto unused in this field, namely an asynchronous system for the regulation of the passage of data from the analogue computer to the A-D converters and an interpolation system at the output of the digital computer. The philosophy of linkage construction is considered and the reasons behind the choice of this method are made explicit. The consequences in terms of hardware are examined at length and finally the future prospects of the scheme are estimated.

A RAPID IODINE RADIOCHEMICAL PROCEDURE

A radiochemical procedure was developed to determine fission yields and radiation characteristics of short-lived iodine fission products. Iodine was separated from other fission products of uranium in less than 10 sec after completion of irradiation. High decontamination factors of iodine from Sn, Sb, Te, Xe, Cs and Ba, and high chemical yields were obtained. The sample was prepared by dissolving uranium peroxide in molten periodic acid; the melt was cooled, ground and mixed with activated carbon. After irradiation, the periodic acid was decomposed by heat and the gaseous iodine formed was collected in carbon tetrachloride or in a cooled counting chamber. Higher temperatures could be used than in conventional aqueous systems, thus enhancing the exchange of carrier and fission product iodine.
