A MICROGRAPHIC STUDY OF CARBONIZATION AND GRAPHITIZATION OF AN EXTRACTED COAL-TAR PITCH  
by J.L. WHITE, J. DUBOIS and C. SOUILLART

European Atomic Energy Community - EURATOM  
Joint Nuclear Research Center - Petten Establishment (Netherlands)  
Luxembourg, January 1969 - 24 Pages - 15 Figures - FB 40

Polarized-light micrography has been employed to investigate the microstructures formed in the carbonization and graphitization of a coal-tar pitch from which the insoluble particles have been removed by solvent extraction. Prominent features in the polarized-light extinction contours are the nodes and crosses, which are identified as four types of linear defects in the stacking of the aromatic layer planes. The coalescence process produces mostly cross-type stacking defects, but the deformation of the plastic mesophase caused by the percolation of gas bubbles results in an increase in the number of stacking defects and the formation of highly ordered regions with many folds in the layer planes. The principal effects of further treatment may be summarized as

**THE EFFECT OF NICOTINAMIDE ON X-IRRADIATED SUSPENSION CULTURES OF RAT BONE MARROW CELLS** by J.F. WHITFIELD, T. YOUNG and H. BROHEE

European Atomic Energy Community - EURATOM  
Joint Nuclear Research Center  
Ispra Establishment - Italy  
Biology Department  
Brussels, May 1965 - 16 pages - 7 figures.

P 5353

During the first 6 hours after irradiation (250 to 1500 r) of suspension cultures of rat bone marrow, the nuclei of the various "blast" cells, promyelocytes, myelocytes, normoblasts and cells of the lymphocyte family, lost their reticular structure and became structurally homogeneous. This change could be retarded by adding nicotinamide (0.075M) to the culture immediately after irradiation.

Lactate production was slightly stimulated in both normal and irradiated cultures

by irradiation (500 r). Lactate production was also stimulated by exposure of the cells to nicotinamide.

WHYTE, F., 1966. Dumbarton Rock  
*Scott. J. Geol.*, 2 (1), 107-121

P 4363

A study of the attitude of columnar joints in the Dumbarton Rock basalt suggests that the plug is narrowing downwards and could represent an infilled crater.

At a late stage in the volcano's history, before the emplacement of the plug, subsidence took place along fractures developed around the crater. The narrow strip of pyroclastic rocks and sediments exposed along the north-west shore represents part of this subsided mass.

Chemical analyses of the contact basalt show increasing MgO and H<sub>2</sub>O and decreasing CaO towards the contact. It is thought that the albitised and chloritised contact basalt is due to migration of volatiles towards these contacts.
